

Explore with Variants in design systems

Our short guide on how to use variants when you have to use the same component but different options inside depending on user context. This example does not represent any part of design system but shows how to play with variants during the creation process.

Start:

- 1 . Divide by types: types most often means contexts, component types, web/mobile, or even color themes, u need to decide on this.
- 2 . Then define dynamic set of options inside: icon, action buttons, close action, content arrangement, heading types, there could be a long list of properties.
- 3 . Do not use user contexts when give names for property values or variants. Contexts are unlimited, but you want to limit your library by using only variants of components structure.

Also, “Login modal” such naming approach usually ends badly → “regular-modal” is much better.
